Data Reduction

- Data reduction decreases data
- Benefits of data reduction

Data Reduction

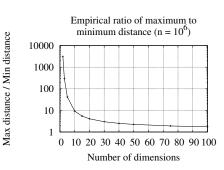

- Data reduction decreases data
- Benefits of data reduction
 - Simpler model
 - Less number of rules
 - Less complex rules, i.e., involving less number of attributes
 - Faster algorithms
 - Easier visualization
 - Avoids overfitting

Data Reduction

- Data reduction decreases data
- Benefits of data reduction
 - Simpler model
 - Less number of rules
 - Less complex rules, i.e., involving less number of attributes
 - Faster algorithms
 - Easier visualization
 - Avoids overfitting
- Important ways of data reduction
 - Dimensionality reduction
 - Numerosity reduction
 - Data discretization
 - Data modeling
 - Feature selection

Dimensionality Reduction

- Dimensionality reduction reduces the number of dimensions
- New dimensions are generally different from original ones
- Curse of dimensionality
 - Data becomes too sparse as dimensions increase
 - Data is mostly at the boundaries
 - Classification: Not enough data to create good models or methods
 - Clustering: Density becomes irrelevant and distance between points becomes similar

Singular Value Decomposition (SVD)

Singular value decomposition is factorization of a matrix

$$A = U\Sigma V^T$$

- If A is of size $m \times n$, then U is $m \times m$, V is $n \times n$ and Σ is $m \times n$
- Columns of U are eigenvectors of AA^T
 - Left singular vectors
 - $UU^T = I_m$ (orthonormal)
- Columns of V are eigenvectors of A^TA
 - Right singular vectors
 - $V^T V = I_n$ (orthonormal)
- σ_{ii} are the singular values
 - Σ is diagonal
 - Singular values are positive square roots of eigenvalues of AA^T or A^TA
- $\sigma_{11} \ge \sigma_{22} \ge \cdots \ge \sigma_{nn}$ (assuming *n* singular values)

Transformation using SVD

Transformed data

$$T = AV = U\Sigma$$

- V is called SVD transform matrix
- Essentially, T is just a rotation of A
- Dimensionality of T is n
- n different basis vectors than the original space
- Columns of V give the basis vectors in rotated space

Transformation using SVD

Transformed data

$$T = AV = U\Sigma$$

- V is called SVD transform matrix
- Essentially, T is just a rotation of A
- Dimensionality of T is n
- n different basis vectors than the original space
- Columns of V give the basis vectors in rotated space
- V shows how each object can be represented as a linear combination of other objects
- U shows how each dimension can be represented as a linear combination of other dimensions

Transformation using SVD

Transformed data

$$T = AV = U\Sigma$$

- V is called SVD transform matrix
- Essentially, T is just a rotation of A
- Dimensionality of T is n
- n different basis vectors than the original space
- Columns of V give the basis vectors in rotated space
- V shows how each object can be represented as a linear combination of other objects
- U shows how each dimension can be represented as a linear combination of other dimensions
- Lengths of vectors are preserved

$$||\vec{a_i}||_2 = ||\vec{t_i}||_2$$

SVD of Real Symmetric Matrix

- A is real symmetric of size $n \times n$
- \bullet $A = A^T$
- U = V since $A^T A = AA^T = A^2$

$$A = Q\Sigma Q^T$$

- Q is of size $n \times n$ and contains eigenvectors of A^2
- This is called spectral decomposition of A
- Σ contains n singular values
- Eigenvectors of A = eigenvectors of A^2
- Eigenvalues of A =square root of eigenvalues of A^2
- Eigenvalues of A = singular values of A

Example

$$A\begin{bmatrix} 2 & 4 & 1 \\ 1 & 3 & 0 \\ 5 & 2 & 1 \\ 0 & 0 & 7 \\ 3 & 3 & 3 \end{bmatrix} = U\begin{bmatrix} -0.41 & 0.29 & 0.49 & -0.41 & -0.56 \\ -0.23 & 0.27 & 0.48 & 0.77 & 0.18 \\ -0.48 & 0.36 & -0.71 & 0.23 & -0.25 \\ -0.47 & -0.83 & 0.02 & 0.18 & -0.19 \\ -0.55 & 0.05 & 0.01 & -0.37 & 0.73 \end{bmatrix}$$

$$\times \Sigma \begin{bmatrix} 9.30 & 0 & 0 \\ 0 & 6.47 & 0 \\ 0 & 0 & 2.91 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \times V^{T} \begin{bmatrix} -0.55 & 0.44 & -0.70 \\ -0.53 & 0.45 & 0.70 \\ -0.63 & -0.77 & 0.01 \end{bmatrix}^{T}$$

Transformed Data

$$T = AV = U\Sigma = \begin{bmatrix} 2 & 4 & 1 \\ 1 & 3 & 0 \\ 5 & 2 & 1 \\ 0 & 0 & 7 \\ 3 & 3 & 3 \end{bmatrix} \times \begin{bmatrix} -0.55 & 0.44 & -0.70 \\ -0.53 & 0.45 & 0.70 \\ -0.63 & -0.77 & 0.01 \end{bmatrix}$$
$$= \begin{bmatrix} -3.89 & 1.93 & 1.44 \\ -2.16 & 1.80 & 1.42 \\ -4.47 & 2.36 & -2.08 \\ -4.45 & -5.39 & 0.08 \\ -5.18 & 0.38 & 0.05 \end{bmatrix}$$
Lengths = [4.58, 3.16, 5.47, 7.00, 5.19]

Compact Form

$$A \begin{bmatrix} 2 & 4 & 1 \\ 1 & 3 & 0 \\ 5 & 2 & 1 \\ 0 & 0 & 7 \\ 3 & 3 & 3 \end{bmatrix} = U \begin{bmatrix} -0.41 & 0.29 & 0.49 \\ -0.23 & 0.27 & 0.48 \\ -0.48 & 0.36 & -0.71 \\ -0.47 & -0.83 & 0.02 \\ -0.55 & 0.05 & 0.01 \end{bmatrix} \times V^{T} \begin{bmatrix} -0.55 & 0.44 & -0.70 \\ -0.53 & 0.45 & 0.70 \\ -0.63 & -0.77 & 0.01 \end{bmatrix}^{T}$$

- If A is of size $m \times n$, then U is $m \times n$, V is $n \times n$ and Σ is $n \times n$
- Works because there at most n non-zero singular values in Σ

Dimensionality Reduction using SVD

$$A = U\Sigma V^T = \sum_{i=1}^n (u_i \sigma_{ii} v_i^T)$$

- Use only *k* dimensions
- Retain first k columns for U and V and first k values for Σ
- First *k* columns of *V* give the basis vectors in reduced space

$$A_k \approx \sum_{i=1}^k (u_i \sigma_{ii} v_i^T) = U_{1...k} \Sigma_{1...k} V_{1...k}^T$$
$$T_k \approx A V_{1...k}$$

Reduced Dimensionality

$$A \approx A_k = U_k \begin{bmatrix} -0.41 & 0.29 \\ -0.23 & 0.27 \\ -0.48 & 0.36 \\ -0.47 & -0.83 \\ -0.55 & 0.05 \end{bmatrix} \times \Sigma \begin{bmatrix} 9.30 & 0 \\ 0 & 6.47 \end{bmatrix} \times V^T \begin{bmatrix} -0.55 & 0.44 \\ -0.53 & 0.45 \\ -0.63 & -0.77 \end{bmatrix}^T$$

$$= \begin{bmatrix} 3.01 & 2.97 & 0.98 \\ 2.00 & 1.98 & -0.01 \\ 3.52 & 3.48 & 1.02 \\ 0.05 & -0.05 & 6.99 \\ 3.03 & 2.96 & 2.99 \end{bmatrix}$$

$$\begin{bmatrix} -3.89 & 1.93 \\ -2.16 & 1.80 \end{bmatrix}$$

$$T \approx T_k = AV_k = U_k \Sigma_k = \begin{bmatrix} -3.89 & 1.93 \\ -2.16 & 1.80 \\ -4.47 & 2.36 \\ -4.45 & -5.39 \\ -5.18 & 0.38 \end{bmatrix}$$

Reduced Lengths = [4.34, 2.82, 5.06, 6.99, 5.19]

Length Ratios = [0.95, 0.89, 0.92, 1.00, 1.00]

Best Approximation

• Frobenius norm of a matrix C of size $n \times m$ is

$$||C||_F = \sqrt{\sum_{i=1}^n \sum_{j=1}^m C_{ij}^2}$$

Best Approximation

• Frobenius norm of a matrix C of size $n \times m$ is

$$||C||_F = \sqrt{\sum_{i=1}^n \sum_{j=1}^m C_{ij}^2}$$

- Consider any rank-k approximation A_k of A
- SVD produces A_k* that minimizes the Frobenius norm of the difference
 - Best in terms of sum squared error

$$A_k^* = \arg\min_{A_k: rank = k} ||A - A_k||_F$$

• There is no easy answer

- There is no easy answer
- Concept of energy of a dataset
- Total energy is sum of squares of singular values (aka spread or variance)

$$E = \sum_{i=1}^{n} \sigma_{ii}^2$$

• Retain k dimensions such that p% of the energy is retained

$$E_k = \sum_{i=1}^k \sigma_{ii}^2$$

$$E_k/E \ge p$$

- There is no easy answer
- Concept of energy of a dataset
- Total energy is sum of squares of singular values (aka spread or variance)

$$E = \sum_{i=1}^{n} \sigma_{ii}^2$$

• Retain k dimensions such that p% of the energy is retained

$$E_k = \sum_{i=1}^k \sigma_{ii}^2$$

$$E_k/E \ge p$$

• Generally, p is between 80 % to 95 %

- There is no easy answer
- Concept of energy of a dataset
- Total energy is sum of squares of singular values (aka spread or variance)

$$E = \sum_{i=1}^{n} \sigma_{ii}^2$$

• Retain k dimensions such that p% of the energy is retained

$$E_k = \sum_{i=1}^k \sigma_{ii}^2$$

$$E_k/E \geq p$$

- Generally, p is between 80 % to 95 %
- In the above example, k=1 (resp. k=2) retains 63 % (resp. 94 %) of the energy

- There is no easy answer
- Concept of energy of a dataset
- Total energy is sum of squares of singular values (aka spread or variance)

$$E = \sum_{i=1}^{n} \sigma_{ii}^2$$

• Retain k dimensions such that p% of the energy is retained

$$E_k = \sum_{i=1}^k \sigma_{ii}^2$$
$$E_k / E \ge p$$

- Generally, p is between 80 % to 95 %
- In the above example, k=1 (resp. k=2) retains 63 % (resp. 94 %) of the energy
- Running time: O(m.n.r) for A of size $m \times n$ and rank r

Principal Component Analysis (PCA)

- Way of identifying patterns in data
 - How input basis vectors are correlated for the given data
- A transformation from a set of (possibly) correlated axes to another set of uncorrelated axes
- Orthogonal linear transformation (i.e., rotation)
- New axes are principal components
- First principal component produces projections that are best in the squared error sense
- Optimal least squares solution

Algorithm

- Mean center the data (optional)
- Compute the covariance matrix of the dimensions
- Find eigenvectors of covariance matrix
- Sort eigenvectors in decreasing order of eigenvalues
- Project onto eigenvectors in order

Algorithm

- Mean center the data (optional)
- Compute the *covariance matrix* of the dimensions
- Find eigenvectors of covariance matrix
- Sort eigenvectors in decreasing order of eigenvalues
- Project onto eigenvectors in order
- Assume data matrix is B of size $m \times n$
- ullet For each dimension, compute mean μ_i
- Mean center B by subtracting μ_i from each column i to get A
- Compute covariance matrix C of size $n \times n$
 - If mean centered, $C = A^T A$
- ullet Find eigenvectors and corresponding eigenvalues (V, E) of C
- Sort eigenvalues such that $e_1 \geq e_2 \geq \cdots \geq e_n$
- Project step-by-step onto the principal components $\vec{v_1}, \vec{v_2}, \ldots$, etc.

Example

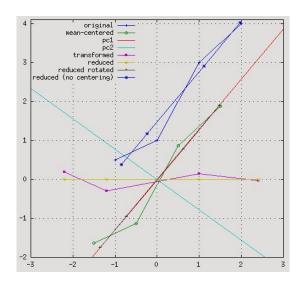

$$B = \begin{bmatrix} 2 & 4 \\ 1 & 3 \\ 0 & 1 \\ -1 & 0.5 \end{bmatrix}; \mu(B) = \begin{bmatrix} 0.500 & 2.125 \end{bmatrix}$$

$$\therefore A = \begin{bmatrix} 1.5 & 1.875 \\ 0.5 & 0.875 \\ -0.5 & -1.125 \\ -1.5 & -1.625 \end{bmatrix} \text{ and, } C = A^{T}A = \begin{bmatrix} 5.000 & 6.250 \\ 6.250 & 8.187 \end{bmatrix}$$

Eigenvectors
$$V = \begin{bmatrix} 0.613 & -0.789 \\ 0.789 & 0.613 \end{bmatrix}$$
; eigenvalues $E = \begin{bmatrix} 13.043 \\ 0.143 \end{bmatrix}$

Transformed data
$$T = AV = \begin{bmatrix} 2.400 & -0.034 \\ 0.997 & 0.142 \\ -1.195 & -0.295 \\ -2.203 & 0.187 \end{bmatrix}$$

Visual Example

• Also known as Karhunen-Loève transform (KLT)

- Also known as Karhunen-Loève transform (KLT)
- Works for L₂ distances only as others are not invariant to rotation

- Also known as Karhunen-Loève transform (KLT)
- Works for L₂ distances only as others are not invariant to rotation
- Mean-centering
 - Easier way to compute covariance: A^TA is covariance matrix
 - Allows use of SVD to compute PCA

- Also known as Karhunen-Loève transform (KLT)
- Works for L₂ distances only as others are not invariant to rotation
- Mean-centering
 - Easier way to compute covariance: A^TA is covariance matrix
 - Allows use of SVD to compute PCA
- Can be done using SVD
 - Eigenvector matrix V of C is really the SVD transform matrix V for A
 - Different from SVD of B though

- Also known as Karhunen-Loève transform (KLT)
- Works for L₂ distances only as others are not invariant to rotation
- Mean-centering
 - Easier way to compute covariance: A^TA is covariance matrix
 - Allows use of SVD to compute PCA
- Can be done using SVD
 - Eigenvector matrix V of C is really the SVD transform matrix V for A
 - Different from SVD of B though
- How many dimensions to retain?
 - Based on energy (similar to SVD)
 - Total energy is sum of eigenvalues e_i
 - \bullet Retain k dimensions such that $80-95\,\%$ of the energy is retained

- Also known as Karhunen-Loève transform (KLT)
- Works for L₂ distances only as others are not invariant to rotation
- Mean-centering
 - Easier way to compute covariance: A^TA is covariance matrix
 - Allows use of SVD to compute PCA

- How many dimensions to retain?
 - Based on energy (similar to SVD)
 - Total energy is sum of eigenvalues e_i
 - ullet Retain k dimensions such that $80-95\,\%$ of the energy is retained
 - ullet In the above example, k=1 retains $98.91\,\%$ of the energy
- Running time: $O(mn^2 + n^3)$ for A of size $m \times n$

Numerosity Reduction

• Numerosity reduction reduces the volume of data

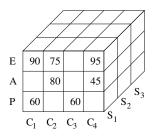

Numerosity Reduction

- Numerosity reduction reduces the volume of data
- Reduction in number of data objects
- Compression
- Modeling
- Discretization

Aggregation

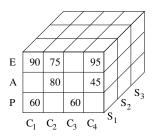

- Considers a set of data objects having some similar attribute(s)
- Aggregates some other attribute(s) into single value(s)
- Example: sum, average
- Benefits of aggregation
 - Aggregate value has less variability
 - Absorbs individual errors
 - Reduces noise

Data Cube

- For multi-dimensional datasets, aggregation can happen along different dimensions
- Data cubes are essentially multi-dimensional arrays
- Each cell or face or lower dimensional surface represents a certain projection operation

Data Cube

- For multi-dimensional datasets, aggregation can happen along different dimensions
- Data cubes are essentially multi-dimensional arrays
- Each cell or face or lower dimensional surface represents a certain projection operation
- Aggregation can also happen along different resolutions in each dimension

- A sample is a representative if it has (approximately) the same property of interest as the full dataset
- Sampling approaches

- A sample is a representative if it has (approximately) the same property of interest as the full dataset
- Sampling approaches
- Sampling without replacement (SRSWOR): produces population
- Sampling with replacement (SRSWR): can be picked more than once

- A sample is a representative if it has (approximately) the same property of interest as the full dataset
- Sampling approaches
- Sampling without replacement (SRSWOR): produces population
- Sampling with replacement (SRSWR): can be picked more than once
- Simple random sampling
- For different types of objects, stratified sampling
 - Picks equal or representative number of objects from each group

- A sample is a representative if it has (approximately) the same property of interest as the full dataset
- Sampling approaches
- Sampling without replacement (SRSWOR): produces population
- Sampling with replacement (SRSWR): can be picked more than once
- Simple random sampling
- For different types of objects, stratified sampling
 - Picks equal or representative number of objects from each group
- Sample size
 - Sample should have enough data to capture variability

- A sample is a representative if it has (approximately) the same property of interest as the full dataset
- Sampling approaches
- Sampling without replacement (SRSWOR): produces population
- Sampling with replacement (SRSWR): can be picked more than once
- Simple random sampling
- For different types of objects, stratified sampling
 - Picks equal or representative number of objects from each group
- Sample size
 - Sample should have enough data to capture variability
- Progressive sampling or adaptive sampling
 - Start with a small sample size
 - Keep on increasing till it is acceptable

Histograms

- Method of discretizing the data
- Mostly useful for one-dimensional data
- Equi-width histograms: bins are equally spaced apart
- Equi-height (equi-depth) histograms: each bin has the same height

Histograms

- Method of discretizing the data
- Mostly useful for one-dimensional data
- Equi-width histograms: bins are equally spaced apart
- Equi-height (equi-depth) histograms: each bin has the same height
- MaxDiff histograms
 - Values are first sorted
 - To get b bins, the largest b-1 differences are made bin boundaries

Central tendency measures

Mean: may be weightedMedian: "middle" value

• Mode: dataset may be unimodal or multimodal

Midrange:

Central tendency measures

Mean: may be weightedMedian: "middle" value

• Mode: dataset may be unimodal or multimodal

• Midrange: average of largest and smallest value

- Central tendency measures

 - Cannot be computed by partitioning the dataset
 - Example: median
- Graphical measures help in data visualization

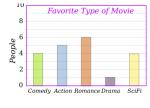

• Histogram:

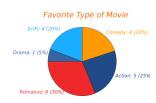

- Histogram: frequency versus grouped values
- Bar chart:

- Histogram: frequency versus grouped values
- Bar chart: histograms where bins are categorical
- Pie chart:

- Histogram: frequency versus grouped values
- Bar chart: histograms where bins are categorical
- Pie chart: relative frequencies shown as secalert in a circle

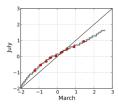

• Quantile plot:

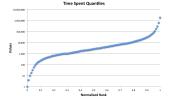

- Quantile plot: quantiles against value
- Quantile-quantile plot (q-q plot):

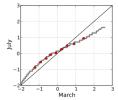

- Quantile plot: quantiles against value
- Quantile-quantile plot (q-q plot): quantiles against quantiles

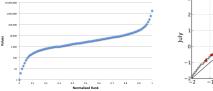

- Quantile plot: quantiles against value
- Quantile-quantile plot (q-q plot): quantiles against quantiles

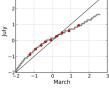

Scatter plot:

- Quantile plot: quantiles against value
- Quantile-quantile plot (q-q plot): quantiles against quantiles

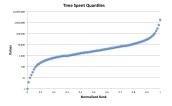

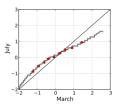

Scatter plot: values of one variable against another

Time Spent Quantiles

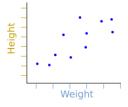

Scatter plot matrix:

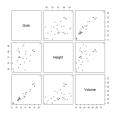

- Quantile plot: quantiles against value
- Quantile-quantile plot (q-q plot): quantiles against quantiles

- Scatter plot: values of one variable against another
- Scatter plot matrix: n^2 scatter plots for n variables

Regression

- Aim is to describe how the response variable Y is generated based on a set of k predictors, denoted by X
- Produces a model of Y

Regression

- Aim is to describe how the response variable Y is generated based on a set of k predictors, denoted by X
- \bullet Produces a model of Y
- Can predict missing values
- The general form of regression model is

$$Y = f(X) + \varepsilon$$

- The function f can be chosen using domain knowledge
- For *linear regression*, f is linear
- ε encodes the *error* (includes *noise*) terms associated with each observation

Linear Regression

- The function f is chosen to be linear
- The response variable depends only linearly with the predictor variables
- The general form of linear regression model is

$$Y = XW + \varepsilon$$

- W are the regression coefficients or weights on the predictors
- Sizes of matrices

Linear Regression

- The function f is chosen to be linear
- The response variable depends only linearly with the predictor variables
- The general form of linear regression model is

$$Y = XW + \varepsilon$$

- W are the regression coefficients or weights on the predictors
- Sizes of matrices
 - $Y: n \times 1$
 - X: n × k
 - W: k × 1
 - ε : $n \times 1$

Linear Regression

- The function f is chosen to be linear
- The response variable depends only linearly with the predictor variables
- The general form of linear regression model is

$$Y = XW + \varepsilon$$

- W are the regression coefficients or weights on the predictors
- Sizes of matrices
 - $Y: n \times 1$
 - X: n × k
 - W: k × 1
 - ε : $n \times 1$
- W can be solved through least squares method

Feature Selection

- Feature selection or attribute selection is different from dimensionality reduction, as it retains original attributes
- Aims to remove redundant and irrelevant features

Feature Selection

- Feature selection or attribute selection is different from dimensionality reduction, as it retains original attributes
- Aims to remove redundant and irrelevant features
- Feature weighting: Variant of feature selection
 - SVM does it naturally

• Three main approaches

- Three main approaches
- Filter
 - Features chosen before the algorithm
 - These use criteria that are independent of the algorithm
 - Entropy, correlation etc.

- Three main approaches
- Filter
 - Features chosen before the algorithm
 - These use criteria that are independent of the algorithm
 - Entropy, correlation etc.

Wrapper

- Feature selection is targeted to the algorithm that is used
- Training error is reduced

- Three main approaches
- Filter
 - Features chosen before the algorithm
 - These use criteria that are independent of the algorithm
 - Entropy, correlation etc.

Wrapper

- Feature selection is targeted to the algorithm that is used
- Training error is reduced

- Embedded
 - Algorithm has built-in feature selection strategy
 - Example: decision trees I ASSO regression

• Total number of possibilities is

- Total number of possibilities is $2^n 1$ (-1)
- Some feature selection algorithms do it using a single shot
 - Example: Relief algorithm

- Total number of possibilities is $2^n 1$ (-1)
- Some feature selection algorithms do it using a single shot
 - Example: Relief algorithm
- Otherwise, systematically add a feature to the empty set
- Or, systematically delete a feature from the full set

- Total number of possibilities is $2^n 1$ (-1)
- Some feature selection algorithms do it using a single shot
 - Example: Relief algorithm
- Otherwise, systematically add a feature to the empty set
- Or, systematically delete a feature from the full set
- Greedy approach

- Total number of possibilities is $2^n 1$ (-1)
- Some feature selection algorithms do it using a single shot
 - Example: Relief algorithm
- Otherwise, systematically add a feature to the empty set
- Or, systematically delete a feature from the full set
- Greedy approach
- Define some error criterion
 - Example: mutual information I(X, Y) = KL(p(x, y)|p(x)p(y))

- Total number of possibilities is $2^n 1$ (-1)
- Some feature selection algorithms do it using a single shot
 - Example: Relief algorithm
- Otherwise, systematically add a feature to the empty set
- Or, systematically delete a feature from the full set
- Greedy approach
- Define some error criterion
 - Example: mutual information I(X, Y) = KL(p(x, y)|p(x)p(y))
- Start from empty set of features
- Add the feature that decreases the error the most
- Stop when there is no significant decrease or there is an increase

- Total number of possibilities is $2^n 1$ (-1)
- Some feature selection algorithms do it using a single shot
 - Example: Relief algorithm
- Otherwise, systematically add a feature to the empty set
- Or, systematically delete a feature from the full set
- Greedy approach
- Define some error criterion
 - Example: mutual information I(X, Y) = KL(p(x, y)|p(x)p(y))
- Start from empty set of features
- Add the feature that decreases the error the most
- Stop when there is no significant decrease or there is an increase
- Start from full set of features
- Remove the feature that increases the error the most
- Stop when there is no significant increase or there is a decrease

- Computes a feature score for every feature
- Features with low score can be thresholded away
- They may also be used as feature weights

- Computes a *feature score* for every feature
- Features with low score can be thresholded away
- They may also be used as feature weights
- Feature score is based on similarity with the nearest neighbor

- Computes a *feature score* for every feature
- Features with low score can be thresholded away
- They may also be used as feature weights
- Feature score is based on similarity with the nearest neighbor
- ullet Each attribute range is normalised to [0,1]

- Computes a *feature score* for every feature
- Features with low score can be thresholded away
- They may also be used as feature weights
- Feature score is based on similarity with the nearest neighbor
- ullet Each attribute range is normalised to [0,1]
- For feature i, initially the score is $s_i = 0$
- Pick a random object
- Find its nearest hit from the same class and nearest miss from the other class

- Computes a feature score for every feature
- Features with low score can be thresholded away
- They may also be used as feature weights
- Feature score is based on similarity with the nearest neighbor
- ullet Each attribute range is normalised to [0,1]
- For feature i, initially the score is $s_i = 0$
- Pick a random object
- Find its nearest hit from the same class and nearest miss from the other class
- Update the score of feature *i* as

$$s_i = s_i - diff_i(\text{nearest-hit}) + diff_i(\text{nearest-miss})$$

• Difference function is Euclidean (L_1 can also be used)

- Computes a feature score for every feature
- Features with low score can be thresholded away
- They may also be used as feature weights
- Feature score is based on similarity with the nearest neighbor
- ullet Each attribute range is normalised to [0,1]
- For feature i, initially the score is $s_i = 0$
- Pick a random object
- Find its nearest hit from the same class and nearest miss from the other class
- Update the score of feature *i* as

$$s_i = s_i - diff_i(\text{nearest-hit}) + diff_i(\text{nearest-miss})$$

- Difference function is Euclidean (L_1 can also be used)
- Done for *m* random objects

- Computes a feature score for every feature
- Features with low score can be thresholded away
- They may also be used as feature weights
- Feature score is based on similarity with the nearest neighbor
- ullet Each attribute range is normalised to [0,1]
- For feature i, initially the score is $s_i = 0$
- Pick a random object
- Find its nearest hit from the same class and nearest miss from the other class
- Update the score of feature *i* as

$$s_i = s_i - diff_i(\text{nearest-hit}) + diff_i(\text{nearest-miss})$$

- Difference function is Euclidean (L_1 can also be used)
- Done for *m* random objects
- ullet All features with score less than threshold au are removed

• k nearest neighbors

- *k* nearest neighbors
- If nearest neighbor has a missing value for the attribute, difference

- *k* nearest neighbors
- If nearest neighbor has a missing value for the attribute, difference
 - can be ignored

- k nearest neighbors
- If nearest neighbor has a missing value for the attribute, difference
 - can be ignored
 - is set to 1 1/# values-of-attribute

- k nearest neighbors
- If nearest neighbor has a missing value for the attribute, difference
 - can be ignored
 - is set to 1 1/# values-of-attribute
 - is estimated as 1 P(value|class(nearest-neighbor))

- k nearest neighbors
- If nearest neighbor has a missing value for the attribute, difference
 - can be ignored
 - is set to 1 1/# values-of-attribute
 - is estimated as 1 P(value|class(nearest-neighbor))
- For multiple classes

- k nearest neighbors
- If nearest neighbor has a missing value for the attribute, difference
 - can be ignored
 - is set to 1-1/# values-of-attribute
 - is estimated as 1 P(value|class(nearest-neighbor))
- For multiple classes
 - Nearest miss can be taken from any other class

- k nearest neighbors
- If nearest neighbor has a missing value for the attribute, difference
 - can be ignored
 - is set to 1-1/# values-of-attribute
 - is estimated as 1 P(value|class(nearest-neighbor))
- For multiple classes
 - Nearest miss can be taken from any other class
 - Nearest miss is an average of nearest misses from every other class
